

Winning Space Race with Data Science

Anastasija Prisjaznuka 20.11.2021

Outline

- Executive Summary
- Introduction
- Methodology
- Results
- Conclusion
- Appendix

Executive Summary

- Collected data from public SpaceX API
 and SpaceX Wikipedia page. Created labels column 'class' which classifies successful landings.
 Explored data using SQL, visualization, folium maps, and dashboards. Gathered relevant column s to be used as features. Changed all categorical variables to binary using one hot encoding. Standardized data and used GridSearchCV to find best parameters for machine learning models. Visualize accuracy score of all models.
- Four machine learning models were produced: Logistic Regression, Support Vector Machine, Decision Tree Classifier, and K Nearest Neighbors.
- All produced similar results with accuracy rate of about 83.33%. All
 models over predicted successful landings. More data is needed for better model determination
 and accuracy.

Introduction

• <u>Background:</u> In this capstone, SpaceX advertises Falcon 9 rocket launches on its website with a cost of 62 million dollars; other providers cost upward of 165 million dollars each, much of the savings is because SpaceX can reuse the first stage.

• <u>The Problem:</u>Therefore if we can determine if the Falcon 9 first stage will land, we can determine the cost of a launch. This information can be used if an alternate company wants to bid against SpaceX for a rocket launch. We will create a machine learning pipeline to predict if the first stage will land given the data from the preceding labs.

Methodology

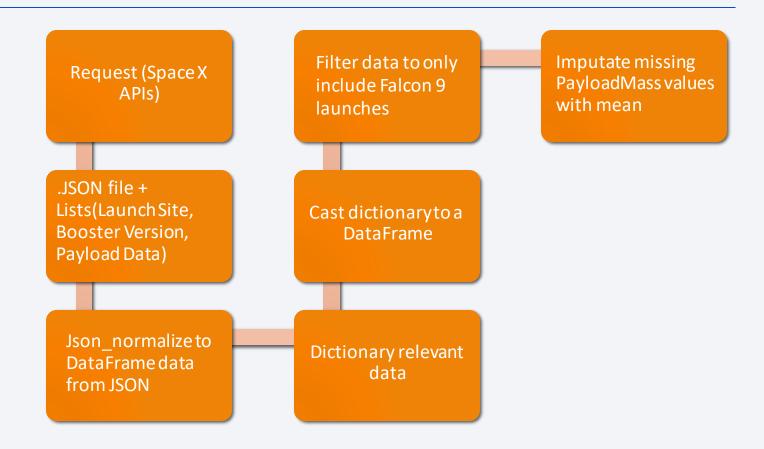

Executive Summary

- Data collection methodology:
 - Combined data from SpaceX public API and SpaceX Wikipedia page
- Perform data wrangling
 - Classifying true landings as successful and unsuccessful otherwise
- Perform exploratory data analysis (EDA) using visualization and SQL
- Perform interactive visual analytics using Folium and Plotly Dash
- Perform predictive analysis using classification models
 - Tuned models using GridSearchCV

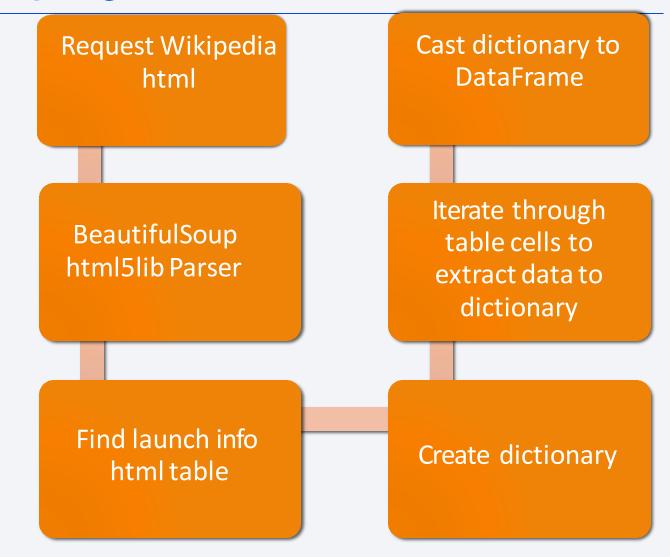

Data Collection

- Data collection process involved a combination of API requests from Space X public API and web scraping data from a table in Space X's Wikipedia entry.
- The next slide will show the flowchart of data collection from API and the one after will show the flowchart of data collection from webscraping.
- Space X API Data Columns:
- FlightNumber, Date, BoosterVersion, PayloadMass, Orbit, LaunchSite, Outcome, Flights, GridFins,
- Reused, Legs, LandingPad, Block, ReusedCount, Serial, Longitude, Latitude
- Wikipedia Webscrape Data Columns:
- Flight No., Launch site, Payload, PayloadMass, Orbit, Customer, Launch outcome, Version Booster, Booster landing, Date, Time

Data Collection – SpaceX API

Data Collection - Scraping

Data Collection-Scraping link

Data Wrangling

- Create a training label with landing outcomes where successful = 1 & failure = 0.
- Outcome column has two components: 'Mission Outcome' 'Landing Location'
- New training label column 'class' with a value of 1 if 'Mission Outcome' is True and
 0 otherwise.

Value Mapping:

- True ASDS, True RTLS, & True Ocean set to -> 1
- None None, False ASDS, None ASDS, False Ocean, False RTLS set to -> 0

EDA with Data Visualization

- Exploratory Data Analysis performed on variables Flight Number, Payload Mass, Launch Site, Orbit, Class and Year.
- Plots Used:
- Flight Number vs. Payload Mass, Flight Number vs. Launch Site, Payload Mass vs. Launch Site, Orbit vs. Success Rate, Flight Number vs. Orbit, Payload vs Orb it, and Success Yearly Trend
- Scatter plots, line charts, and bar plots were used to compare relationships between variables to
- decide if a relationship exists so that they could be used in training the machine learning model

EDA with DATA Visualization link

EDA with SQL

- Loaded data set into IBM DB2 Database.
- Queried using SQL Python integration.
- Queries were made to get a better understanding of the dataset.
- Queried information about launch site names, mission outcomes, various pay load sizes of customers and booster versions, and landing outcomes

EDA with SQL link

Build an Interactive Map with Folium

- Folium maps mark Launch Sites, successful and unsuccessful landings, and a proximity example to key locations: Railway, Highway, Coast, and City.
- This allows us to understand why launch sites may be located where they are. Also visualizes successful landings relative to location.

Build a Dashboard with Plotly Dash

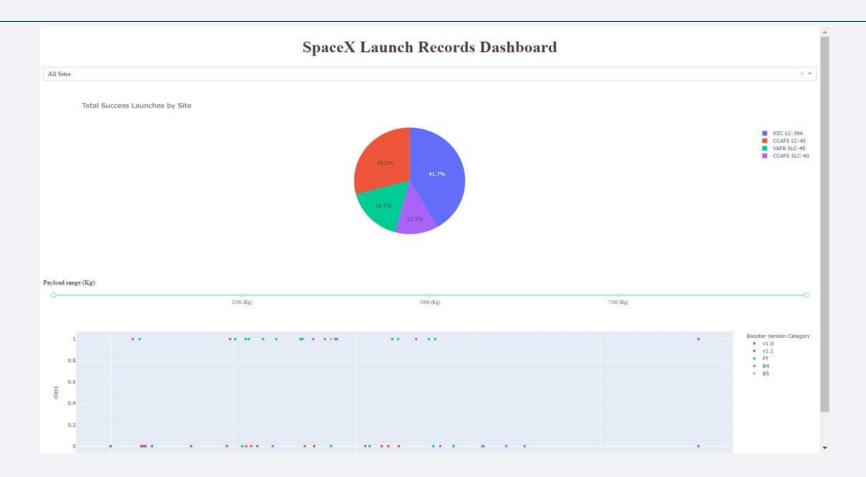

- Dashboard includes a pie chart and a scatter plot.
- Pie chart can be selected to show distribution of successful landings across all launch sites and can be selected to show individual launch site success rates.
- Scatter plot takes two inputs: All sites or individual site and payload mass on a slider between 0 and 10000 kg.
- The pie chart is used to visualize launch site success rate.
- The scatter plot can help us see how success varies across launch sites, payload mass, and
- booster version category.

Predictive
Analysis
(Classificatio
n)

Split label Score models Confusion column on split test Matrix for all 'Class' from set models dataset Use Fit and Barplot to GridSearchCV Transform Decision Tree, compare scores Standard and KNN models of models Scaler GridSearchCV Train_test_spl (cv=10) to find it data optimal parameters

Machine learning link

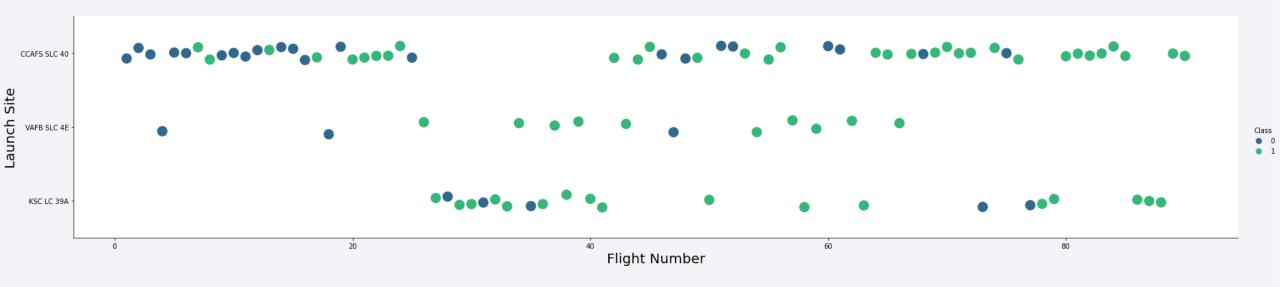

Results

This is a preview of the Plotly dashboard. The following sides will show the results of EDA with visualization, EDA with SQL, Interactive Map with Folium, and finally the results of our model with about 83% accuracy.

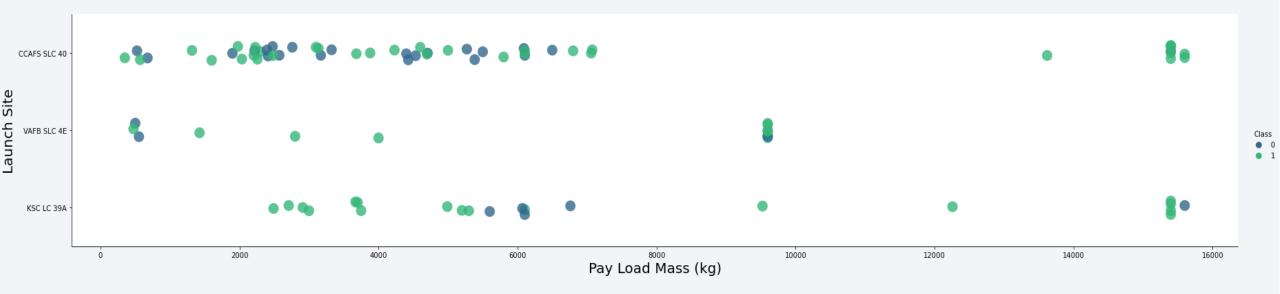

Flight Number vs. Launch Site

- Green indicates successful launch; Purple indicates unsuccessful launch.
- Graphic suggests an increase in success rate over time (indicated in Flight Number). Likely a big breakthrough around flight 20 which significantly increased success rate. CCAFS appears to be the main launch site as it has the most volume.

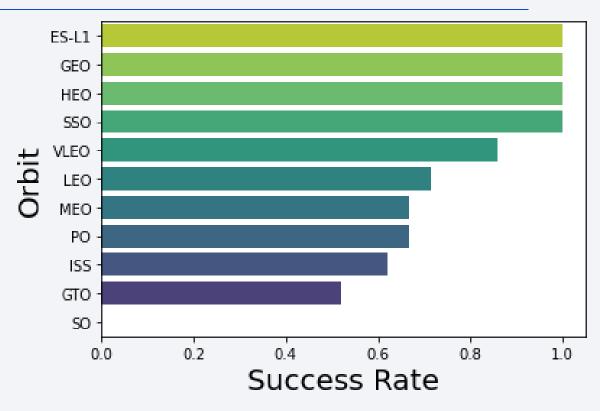

Payload vs. Launch Site

- Green indicates successful launch; Purple indicates unsuccessful launch.
- Payload mass appears to fall mostly between 0-6000 kg. Different launch sites also seem to use different payload mass.

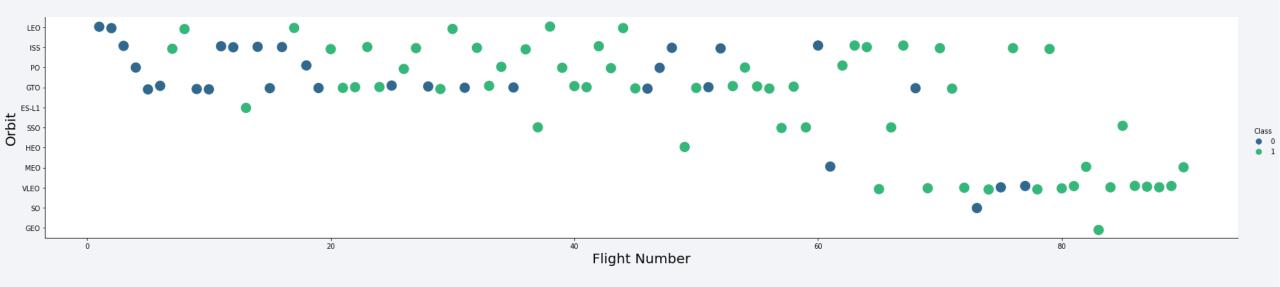

Success Rate vs. Orbit Type

- ES-L1, GEO,
 HEO have 100% success rate (sample si zes in parenthesis)
- SSO has 100% success rate
- VLEO has decent success rate and attempts
- SO has 0% success rate
- GTO has the around
 50% success rate but largest sample

Success Rate Scale with 0 as 0%, 0.6 as 60% 1.0 as 100%

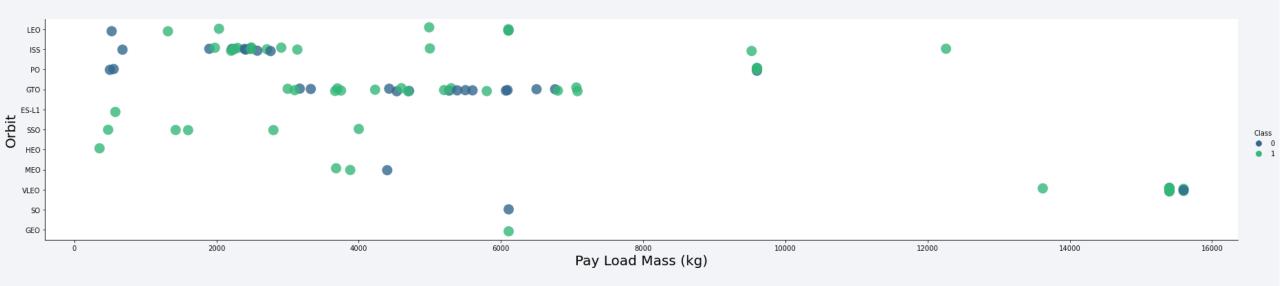

Flight Number vs. Orbit Type

- Green indicates successful launch; Purple indicates unsuccessful launch.
- Launch Orbit preferences changed over Flight
 Number. Launch Outcome seems to correlate with this
 preference.SpaceX started with LEO orbits which saw
 moderate success LEO and returned to VLEO in recent

launches Chasely appears to norform better in lawer

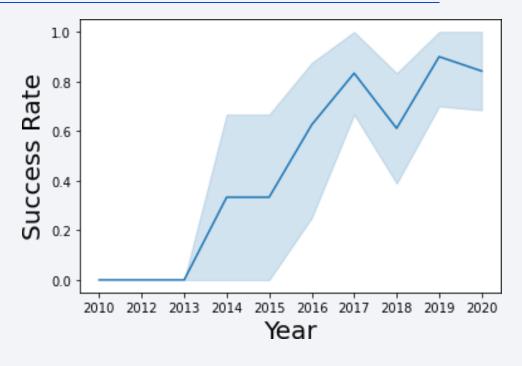

Payload vs. Orbit Type

- Green indicates successful launch; Purple indicates unsuccessful launch.
- Payload mass seems to correlate with orbit LEO and SSO seem to have relatively low payload mass. The other most successful orbit VLEO only has payload mass values in the higher end of the range.

Launch Success Yearly Trend

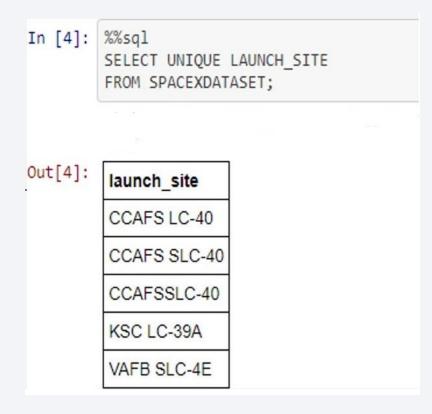

- Success generally increases over time since 2013 with a slight dip in 2018
- Success in recent years at around 80%

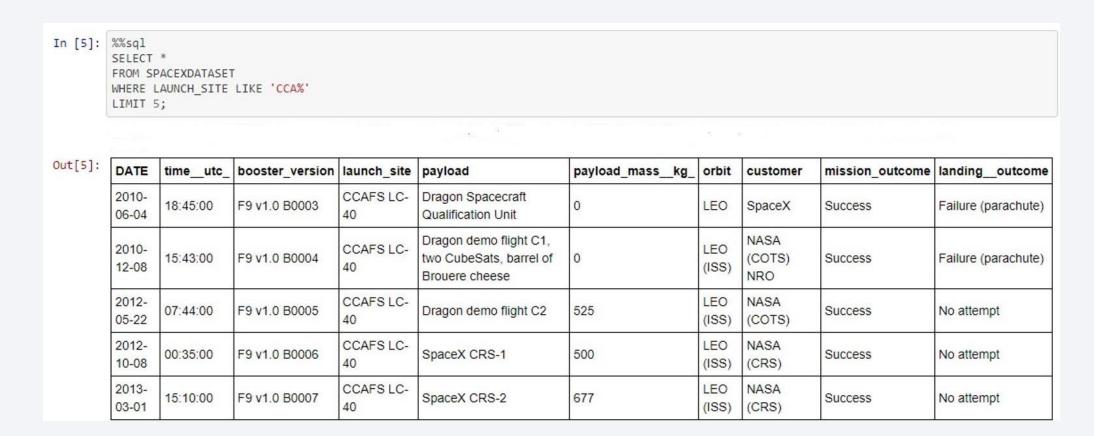

95% confidence interval (light blue shading)

All Launch Site Names

- Query unique launch site names from database.
- CCAFS SLC-40 and CCAFSSLC-40 likely all represent the samelaunch site with data entry errors.
- CCAFS LC-40 was the previous name.
 Likely only 3 unique launch_site
 values: CCAFS SLC-40, KSC LC 39A, VAFB SLC-4E

Launch Site Names Begin with 'CCA'

First five entries in database with Launch Site name beginning with CCA.

Total Payload Mass

```
%%sql
SELECT SUM(PAYLOAD MASS KG ) AS SUM PAYLOAD MASS KG
FROM SPACEXDATASET
WHERE CUSTOMER = 'NASA (CRS)';
sum_payload_mass_kg
45596
```

This query sums the total payload mass in kg where NASA was the customer. CRS stands for Commercial Resupply Services which indicates that these payloads were sent to the International Space Station (ISS).

Average Payload Mass by F9 v1.1

```
%%sql
SELECT AVG(PAYLOAD_MASS__KG_) AS AVG_PAYLOAD_MASS_KG
FROM SPACEXDATASET
WHERE booster_version = 'F9 v1.1'
avg_payload_mass_kg
2928
```

This query calculates the average payload mass or launches which used booster version F9 v1.1 Average payload mass of F9 1.1 is on the low end of our payload mass range

First Successful Ground Landing Date

```
%%sql
SELECT MIN(DATE) AS FIRST_SUCCESS
FROM SPACEXDATASET
WHERE landing outcome = 'Success (ground pad)';
first success
2015-12-22
```

This query returns the first successful ground pad landing date.

First ground pad landing wasn't until the end of 2015.

Successful landings in general appear starting 2014.

Successful Drone Ship Landing with Payload between 4000 and 6000

```
%%sql
SELECT booster_version
FROM SPACEXDATASET
WHERE landing_outcome = 'Success (drone ship)' AND payload_mass_kg_ BETWEEN 4001 AND 5999;
```

booster_version

F9 FT B1022

F9 FT B1026

F9 FT B1021.2

F9 FT B1031.2

This query returns the four booster versions that had successful drone ship landings and a payload mass between 4000 and 6000 noninclusively.

Total Number of Successful and Failure Mission Outcomes

```
%%sql
SELECT mission_outcome, COUNT(*) AS no_outcome
FROM SPACEXDATASET
GROUP BY mission_outcome;
```

mission_outcome	no_outcome
Failure (in flight)	1
Success	99
Success (payload status unclear)	1

This query returns a count of each mission outcome.

SpaceX appears to achieve its mission outcome nearly 99% of the time. This means that most of the landing failures are intended. Interestingly, one launch has an unclear payload status and unfortunately one failed in flight.

Boosters Carried Maximum Payload

- This query returns the booster version s that carried the highest payload mas s of 15600 kg.
- These booster versions are very simila r and all are of the F9 B5 B10xx.x variety.
- This likely indicates payload mass corr elates with the booster version that is used.

```
%%sql
SELECT booster_version, PAYLOAD_MASS__KG_
FROM SPACEXDATASET
WHERE PAYLOAD_MASS__KG_ = (SELECT MAX(PAYLOAD_MASS__KG_) FROM SPACEXDATASET);
```

booster_version	payload_masskg_
F9 B5 B1048.4	15600
F9 B5 B1049.4	15600
F9 B5 B1051.3	15600
F9 B5 B1056.4	15600
F9 B5 B1048.5	15600
F9 B5 B1051.4	15600
F9 B5 B1049.5	15600
F9 B5 B1060.2	15600
F9 B5 B1058.3	15600
F9 B5 B1051.6	15600
F9 B5 B1060.3	15600
F9 B5 B1049.7	15600

2015 Launch Records

```
%%sql
SELECT MONTHNAME(DATE) AS MONTH, landing_outcome, booster_version, PAYLOAD_MASS__KG_, launch_site
FROM SPACEXDATASET
WHERE landing_outcome = 'Failure (drone ship)' AND YEAR(DATE) = 2015;
```

монтн	landing_outcome	booster_version	payload_masskg_	launch_site
January	Failure (drone ship)	F9 v1.1 B1012	2395	CCAFS LC-40
April	Failure (drone ship)	F9 v1.1 B1015	1898	CCAFS LC-40

This query returns the Month, Landing Outcome,
Booster Version, Payload Mass (kg), and Launch site of 2015 launches where stage 1 failed to land on a drone ship. There were two such occurrences.

Rank Landing Outcomes Between 2010-06-04 and 2017-03-20

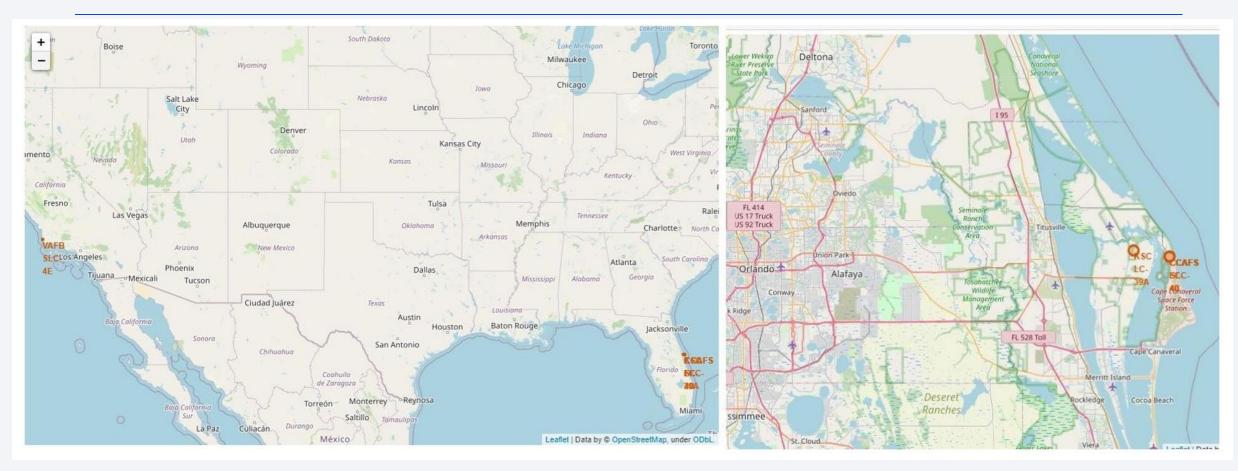

- This query returns a list of successful landings and between 201 0-06-04 and 2017-03-20 inclusively.
- There are two types of successful landing outcomes: drone ship and ground pad landings.
- There were 8 successful landings in total during this time period

```
%%sql
SELECT landing_outcome, COUNT(*) AS no_outcome
FROM SPACEXDATASET
WHERE landing_outcome LIKE 'Succes%' AND DATE BETWEEN '2010-06-04' AND '2017-03-20'
GROUP BY landing_outcome
ORDER BY no_outcome DESC;
```

landing_outcome	no_outcome
Success (drone ship)	5
Success (ground pad)	3

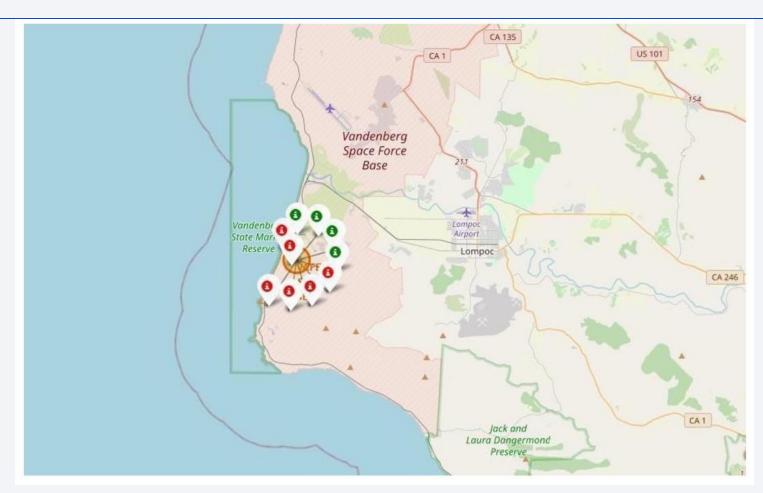

Launch Site Locations

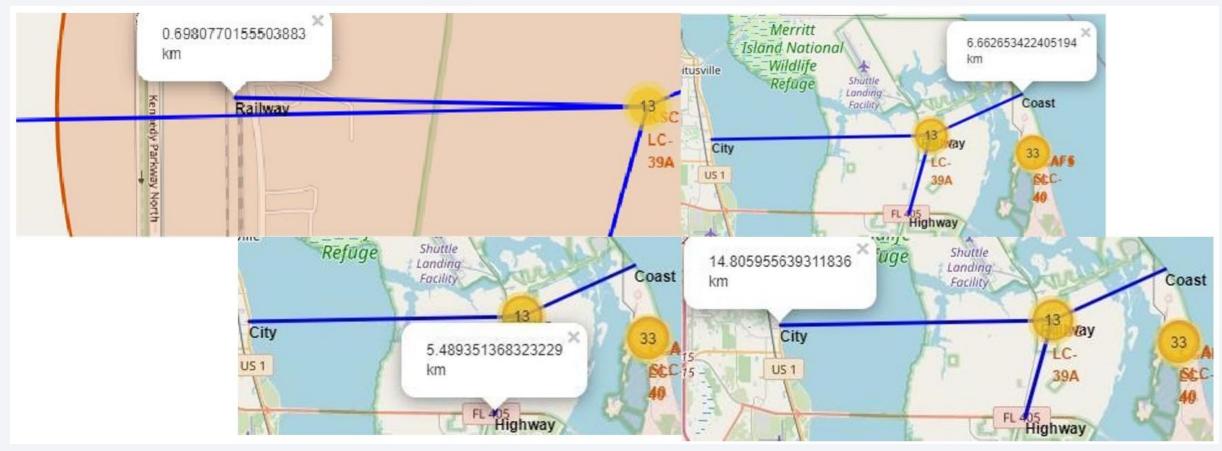

The left map shows all launch sites relative US map. The right map shows the two Florida launch sites since they are very close to each other. All launch sites are near the ocean.

Color-Coded Launch Markers

Clusters on Folium map can be clicked on to display each successful landing (green icon) and failed landing (red icon). In this example VAFB SLC-4E shows 4 successful landings and 6 failed landings.

Key Location Proximities

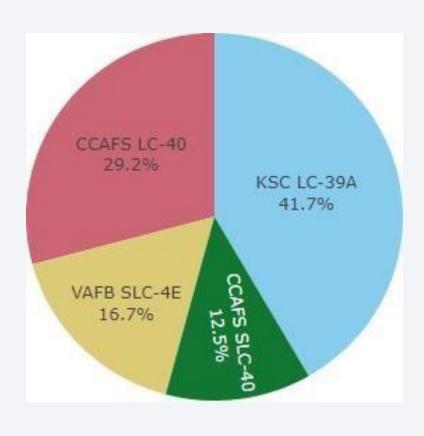

Using KSC LC-39A as an example, launch sites are very close to railways for large part and supply transportation. Launch sites are close to highways for human and supply transport. Launch sites are also close to coasts and relatively far from cities so that launch failures can land in the sea to avoid rockets falling on densely populated areas.

Successful Launches Across Launch Sites

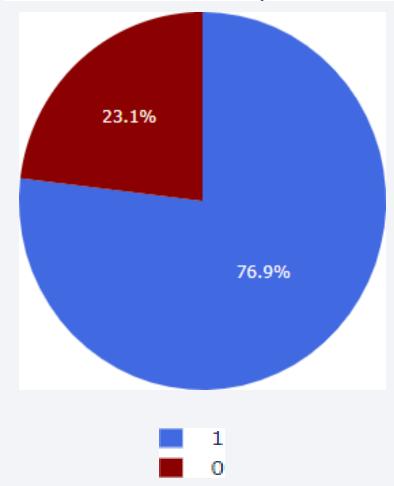

- This is the distribution of successful landings across all launch sites. CCAFS LC-40 is the old name of CCAFS SLC-40 so CCAFS and KSC have the same amount of successful landings, but a majority of the successful landings where performed before the name change.
- VAFB has the smallest share of successful landings. This may be due to smaller sample and increase in difficulty of launching in the west coast.

Highest Success Rate Launch Site

KSC LC-39A
 has the highest success rate with 10 successful landings and 3 failed landings.

KSC LC-39A Success Rate (blue=success)

Payload Mass vs. Success vs. Booster Version Category

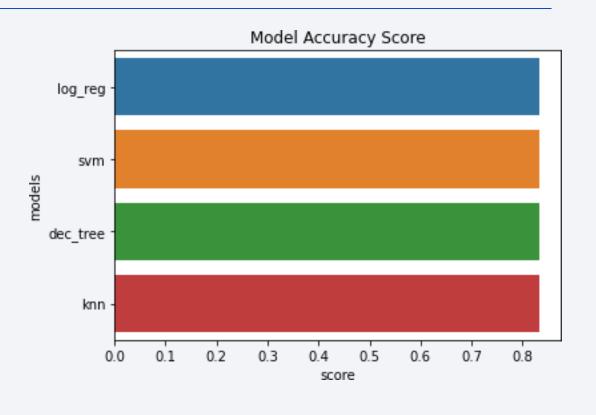

Plotly dashboard has a Payload range selector. However, this is set from 0-10000 instead of the max Payload of 15600. Class indicates 1 for successful landing and 0 for failure. Scatter plot also accounts for booster version category in color and number of launches in point size. In this particular range of 0-6000, interestingly there are two failed landings with payloads of zero kg.

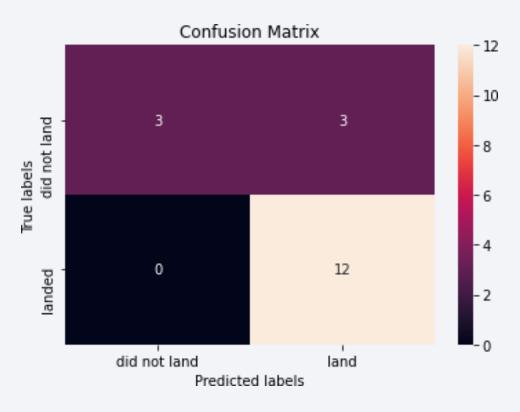

Classification Accuracy

- All models had virtually
 the same accuracy on the test
 set at 83.33% accuracy. It should
 be noted that test
 size is small at only sample size of 18.
- This can cause large variance in accuracy results, such as those in Decision Tree Classifier model in repeated runs.
- We likely need more data to determine the best model.

Confusion Matrix

- Since all models performed the same for the te st set, the confusion matrix is the same across all models. The models pre dicted 12 successful landings when the true label was successful landing.
- The models predicted 3 successful landings when the true label was unsuccessful landings (false positives).
- Our models over predict successful landings

Correct predictions are on a diagonal from top left to bottom right.

Conclusions

- Our task: to develop a machine learning model for Space Y who wants to bid against SpaceX
- The goal of model is to predict when Stage 1 will successfully land to save ~\$100 million USD
- Used data from a public SpaceX API and web scraping SpaceX Wikipedia page.
- Created data labels and stored data into a DB2 SQL database.
- Created a dashboard for visualization.
- We created a machine learning model with an accuracy of 83%.
- Allon Mask can use this model to predict with relatively high accuracy
 whether a launch will have a successful Stage 1 landing before launch to determine
 whether the launch should be made or not.
- If possible more data should be collected to better determine the best machine learning model and improve accuracy.
